

## AI Tools

Well, to start, the tool I used to test was the famous ChatGPT, and honestly, I feel that it is a very useful tool, and even more so for those who know about the topic or the language in which the code is being written. Rather than being a replacement and letting the AI do everything, it can be used as support to complete tasks quickly and efficiently, personally, when I use it, it doesn't usually make mistakes, and if there is one, it's very small, but since I have knowledge of the programming language in which it generates the code, it's easy to correct it, and it doesn't take me more than 10 minutes, when asking it to create an interface or UI, something important is to give as many details as possible and not leave things ambiguous, because that way, it will give a better result, I don't feel that it drastically affects the user experience because, since the AI doesn't do everything but rather accompanies the developer, if there is something that shouldn't be there, the developer can easily fix it while keeping the specifications that the user requested. So, in summary, I feel that AI is very good as a companion because it performs the requested tasks quickly and with great precision based on the details given. That is, in this case, it generates a high-quality interface and correctly maintains the quality attribute that is requested.
